**Clostridium difficile: What Antiseptics and Disinfectants Should We Use?**

**William A. Rutala, Ph.D., M.P.H.**
University of North Carolina (UNC) Health Care System and UNC at Chapel Hill, NC

---

**C. difficile**

- Gram-positive bacillus, anaerobic, spore-forming
- C. difficile is responsible for 15-25% of cases of antibiotic-associated diarrhea and for virtually all cases of antibiotic-associated pseudomembranous colitis.
- Since 2000, a strain of C. difficile identified as NAP1 produces extra toxin and increased amounts of toxins A and B has caused increased morbidity and mortality
- Increasing incidence in U.S.
- Patients can be contaminated from environmental surfaces, shared instrumentation, hospital personnel hands and infected roommates

---

**Environmental Contamination C. difficile**

- 9.3% (85/910) of environmental cultures positive (floors, toilets, toilet seats) for C. difficile. 2.6% (13/497) cultures positive in areas with no know carriers. Kim et al. J Inf Dis 1981;143:42.
- 10% (110/1086) environmental samples were positive for C. difficile in case-associated areas and 2.5% (14/489) in areas with no known cases. Fekety et al. Am J Med 1981;70:907.

---

**Role of Surfaces in Transmission**

Pathogens implicated in transmission via contaminated noncritical surfaces. Patients C/I with these pathogens contaminate the environment and these pathogens survive in the environment.

- Bacteria
  - Methicillin-resistant Staphylococcus aureus
  - Vancomycin-resistant Enterococcus spp.
  - Clostridium difficile
  - Acinetobacter and P. aeruginosa
- Viruses
  - Rotavirus
  - Norovirus
  - SARS coronavirus

---

**Environmental Contamination C. difficile**

- 29% (62/216) environmental samples were positive for C. difficile. 29% (11/38) positive cultures in rooms occupied by asymptomatic patients and 49% (44/90) in rooms with patients who had CDAD. McFarland et al. NEJM 1989;320:204
- 25% (117/466) of cultures positive (<10 CFU) for C. difficile.
- 27% (13/48) of samples were positive for C. difficile. The NAP1 epidemic strain was found in 5 of 6 facilities. Dubberke et al. AJIC 2007;35:315.
**C. difficile Environmental Contamination**

- Frequency: ~10->50%—Stethoscopes, bed frames/rails, call buttons, sinks, hospital charts, toys, floors, windowsills, commodes, toilets, bed sheets, scales, blood pressure cuffs, phones, door handles, electronic thermometers, flow-control devices for IV catheter, feeding tube equipment, bedpan hoppers
- C. difficile spore load is low; 7 studies assessed the spore load and most found <10 colonies on surfaces found to be contaminated. Two studies reported >100; one reported a range of “1->200” and one study sampled several sites with a sponge and found 1,300 colonies C. difficile.

**Role of the Environment**

- 0-25% environmental sites positive-0% hand cultures positive
- 26-50% environmental sites positive-8% hand cultures positive
- >50% environmental sites positive-36% hand cultures positive
- C. difficile incidence data correlated significantly with the prevalence of environmental C. difficile. Fawley et al. Epid Infect 2001;126:343.
- 59% of 35 HCWs were C. difficile positive after direct contact with culture-positive patients.

**Survival**

- Vegetative cells
  - Can survive for at least 24 h on inanimate surfaces
- Spores
  - Spores survive for up to 5 months. $10^6$ CFU of C. difficile inoculated onto a floor; marked decline within 2 days. Kim et al. J Inf Dis 1981;143:42.

**Decreasing Order of Resistance of Microorganisms to Disinfectants/Sterilants**

- Spores
- Mycobacteria
- Non-Enveloped Viruses
- Fungi
- Bacteria
- Enveloped Viruses

**Clostridium difficile: What Antiseptics and Disinfectants Should We Use?**

- Microbiology and epidemiology of C. difficile
- Role of the environment in transmission
- Prevention
  - Disinfectants for environmental disinfection
  - Disinfectants for semicritical equipment disinfection
  - Antiseptics
  - Hand hygiene

**Environmental Surface Disinfection**

Disinfectants and Antiseptics

C. difficile spores at 20 min, Rutala et al, 2006

- No measurable activity (1 C. difficile strain, J9)
  - CHG
  - Vesphere (phenolic)
  - 70% isopropyl alcohol
  - 95% ethanol
  - 3% hydrogen peroxide
  - Clorox disinfecting spray (65% ethanol, 0.6% QUAT)
  - Lysol II disinfecting spray (79% ethanol, 0.1% QUAT)
  - TBQ (0.06% QUAT); QUAT may increase sporulation capacity - Lancet 2000;356:1324
  - Novaplus (10% povidone iodide)
  - Accel (0.5% accelerated hydrogen peroxide)

Disinfectants and Antiseptics

C. difficile spores at 10 and 20 min, Rutala et al, 2006

- ~4 log<sub>10</sub> reduction (5 C. difficile strains including BI-9)
  - Clorox, 1:10, ~6,000 ppm chlorine (but not 1:50, ~1,200 ppm)
  - Clorox Clean-up, ~1,910 ppm chlorine
  - Tilex, ~25,000 ppm chlorine
  - Steris 20 sterilant, 0.2% peracetic acid
  - Cidex, 2.4% glutaraldehyde
  - Cidex-OPA, 0.55% OPA
  - Wavicide, 2.65% glutaraldehyde
  - Aldahol, 3.4% glutaraldehyde and 26% alcohol

Environmental Surface Disinfection

Product-1900-6000ppm chlorine effective (5-10m)

Epidemiological Studies with Chlorine

Fig 1. Times required for the microbicides to inactivate ≥6 log<sub>10</sub> (99.99999%) of the spores tested.
Effect of Hypochlorite on Environmental Contamination and Incidence of *C. difficile*

- In an intervention study, the incidence of CDAD for bone marrow transplant patients decreased significantly, from 8.6 to 3.3 cases per 1000 patient days after the environmental disinfection was switched from QUAT to 1:10 hypochlorite solution in the rooms of patients with CDAD. No reduction in CDAD rates was seen among NS-ICU and medicine patients for whom baseline rates were 3.0 and 1.3 cases per 1000-patient days. Mayfield et al. Clin Inf Dis 2000;31:995.

35% of 1128 environmental cultures were positive for *C. difficile*. To determine how best to decontaminate, a cross-over study conducted. There was a significant decrease of *C. difficile* on one of two medicine wards (8.9 to 5.3 per 100 admissions) using hypochlorite (1,000 ppm) vs. detergent. Wilcox et al. J Hosp Infect 2003;54:109.

Acidified bleach (5,000 ppm) and the highest concentration of regular bleach tested (5,000 ppm) could inactivate all the spores in <10 minutes. Perez et al. AJIC 2005;33:320

Control Measures

- Handwashing (soap and water), contact precautions, and meticulous environmental cleaning with an EPA-registered disinfectant should be effective in preventing the spread of the organism. McFarland et al. NEJM 1989;320:204.
- In units with high endemic *C. difficile* infection rates or in an outbreak setting, use dilute solutions of 5.25-6.15% sodium hypochlorite (e.g., 1:10 dilution of bleach) for routine disinfection. (Category II)
- For semicritical equipment, glutaraldehyde (20m), OPA (12m) and peracetic acid (12m) reliably kills *C. difficile* spores using normal exposure times

For semicritical equipment, glutaraldehyde (20m), OPA (12m) and peracetic acid (12m) reliably kills *C. difficile* spores using normal exposure times.

Risk of Acquiring MRSA, VRE, and *C. difficile* from Prior Room Occupants

- Admission to a room previously occupied by an MRSA-positive patient or VRE-positive patient significantly increased the odds of acquisition for MRSA and VRE (although this route is a minor contributor to overall transmission). Arch Intern Med 2006;166:1945.
- Prior environmental contamination, whether measured via environmental cultures or prior room occupancy by VRE-colonized patients, increases the risk of acquisition of VRE. Clin Infect Dis 2008;46:678.
- Prior room occupant with CDAD is a significant risk for CDAD acquisition. ICACC (K-4194) 2008. Shaughnessy et al.

Environmental Surface Disinfection

Poor Product and/or Poor Practice
Current Issues
Clostridium difficile

- Improve cleaning/disinfecting patient care areas
- Hydrogen peroxide vapor
- Ultraviolet light

Patient Area Cleaning/Disinfecting
PC Carling et al, ICHE 2008;29:1 and ICHE 2008;29:1035

- Monitor cleaning performance using an invisible fluorescent targeting method. Rooms (14 high-risk objects) were marked and evaluated after terminal cleaning.
- Results: 1,605 rooms and 20,646 objects were evaluated in 36 hospitals. Mean proportion of objects cleaned was 48%. Following education and process improvement feedback, cleaning improved to 77%
- Conclusion: Substantial opportunity for improving terminal cleaning/disinfecting activities.

**NOTE.** CI, confidence interval.

Mean proportion of surfaces disinfected at terminal cleaning is ~50%

Environmental Surface Disinfection
Poor Practice
Disinfection of Patient Area: C. difficile

Eckstein et al. BMC Infect Dis 2007;7:61

- Assessed adequacy of cleaning practices in rooms of patients with CDI
- Cultured commonly touched surfaces (bedrails, phones, call buttons, door knobs, bedside tables) in rooms of patients with CDI
- Of 9 rooms of patients with CDI, 100% positive cultures prior to cleaning versus 7 (78%) after cleaning, whereas only 1 had positive cultures after bleach disinfection by research staff
- After educational intervention (stressed high touch objects to be disinfected), rates of environmental contamination after housekeeping cleaning were significantly reduced (90%→20%)

Room Decontamination Units

Hydrogen Peroxide Vapor Decontamination

- Bartels MD et al. J Hosp Infect 2008;70:35. MRSA/Sterinis
- Boyle JM et al. ICHE 2008;29:723. C. difficile/Bioquell

Decontamination with Hydrogen Peroxide Vapor

Boyce et al: ICHE 2008;29:723

- 5 wards with a high incidence of C. difficile
- HPV was injected into sealed wards and individual patient rooms using generators until approx 1 micron film of HP was achieved on the surface
- 11/43 (25.6%) surface samples yielded C. difficile compared to 0/27 (0%) after HPV decontamination
- The incidence of nosocomial CDAD was significantly lower during the intervention period
- Conclusion: HPV was efficacious in eradicating C. difficile from contaminated surfaces

Feasibility of Routinely Using HPV

Boyce et al: ICHE 2009: 30:574

- Used HPV to decontaminate selected rooms (e.g., MRSA, VRE, C. difficile)
- HPV requires room be vacated, cleaned of dirt, and sealed
- 1656 rooms decontaminated with HPV
- Total time from room vacated until ready for the next patient was 270min for HPV and 65min for bleach cleaning
- Despite the greater time for decontamination, HPV decontamination is feasible in a busy hospital

UV Room Decontamination

- Fully automated, self calibrates, activated by hand-held remote
- Room ventilation does not need to be modified
- Uses UV-C (254 nm range) to decontaminate surfaces
- Measures UV reflected from walls, ceilings, floors or other treated areas and calculates the operation time to deliver the programmed lethal dose for pathogens.
- UV sensors determines and targets highly-shadowed areas to deliver measured dose of UV energy
- After UV dose delivered, will power-down and audibly notify the operator
- Reduces colony counts of pathogens by >99.9% within 20 minutes

Clostridium difficile: What Antiseptics and Disinfectants Should We Use?

- Microbiology and epidemiology of C. difficile
- Role of the environment in transmission
- Prevention
  - Disinfectants for environmental disinfection
  - Disinfectants for semicritical equipment disinfection
  - Antiseptics
  - Hand hygiene

Disinfection and Sterilization

EH Spaulding believed that how an object will be disinfected depended on the object’s intended use.

CRITICAL - objects which enter normally sterile tissue or the vascular system or through which blood flows should be sterile.

SEMICRITICAL - objects that touch mucous membranes or skin that is not intact require a disinfection process [high-level disinfection (HLD)] that kills all microorganisms but high numbers of bacterial spores.

NONCRITICAL - objects that touch only intact skin require low-level disinfection.

High Level Disinfection of “Semicritical Objects”

*May cause cosmetic and functional damage
High-Level Disinfection

*C. difficile* spores

- 2% glutaraldehyde for 5 min resulted in 99% or more killing of *C. difficile* spores. Hughes et al. Gastro Endo 1986;32:7.
- 2% glutaraldehyde for 10 or 20 min inactivated *C. difficile* spores using the AOAC test. Rutala et al. ICHE 1993;14:38.
- 2% glutaraldehyde and peracetyl ions inactivated *C. difficile* spores. Wullt et al. ICHE 2003;24:765.

Disinfectants and Antiseptics

*C. difficile* spores at 20 min, Rutala et al, 2006

- ~4 log₁₀ reduction (3 *C. difficile* strains including BI-9)
  - Clorox, 1:10, ~6,000 ppm chlorine (but not 1:50)
  - Clorox Clean-up, ~1,910 ppm chlorine
  - Tilex, ~25,000 ppm chlorine
  - Steris 20 sterilant, 0.35% peracetic acid
  - Cidex, 2.4% glutaraldehyde
  - Cidex-OPA, 0.55% OPA
  - Wavicide, 2.65% glutaraldehyde
  - Aldahol, 3.4% glutaraldehyde and 26% alcohol

High-Level Disinfection

*C. difficile* spores

- 2% glutaraldehyde is effective against *C. difficile* at 20 minutes
- 0.55% ortho-phthalaldehyde is effective against *C. difficile* at 12 minutes
- Steris 20 is effective against *C. difficile* at 10 and 20 minutes

Clostridium difficile: What Antiseptics and Disinfectants Should We Use?

- Microbiology and epidemiology of *C. difficile*
- Role of the environment in transmission
- Prevention
  - Disinfectants for environmental disinfection
  - Disinfectants for equipment disinfection
  - Antiseptics
  - Hand hygiene

Disinfectants and Antiseptics

*C. difficile* spores at 20 min, Rutala et al, 2006

- No measurable activity (1 *C. difficile* strain, J9)
  - CHG-chlorhexidine gluconate
  - Vesphene (phenolic)
  - 70% isopropyl alcohol
  - 95% ethanol
  - 3% hydrogen peroxide
  - Clorox disinfecting spray (85% ethanol, 0.6% QUAT)
  - Lysol II disinfecting spray (79% ethanol, 0.1% QUAT)
  - TBQ (0.06% QUAT); QUAT may increase sporulation capacity- Lancet 2000;356:1324
  - Novaplus (10% povidone iodine)
  - Accel (0.5% hydrogen peroxide)

HAND HYGIENE

Either soap or CHG works as a handwash for removal of *C. difficile*.

ICHE 1994:5-697.

70% isopropyl showed no inactivation of *C. difficile* spores at exposure times of 5m, 15m, and 30m.

Hand Hygiene

- 70% isopropyl showed no inactivation of C. difficile spores at exposure times of 5m, 15m, and 30m. Walt et al. ICHE 2003;24:765.

Objective: Evaluate HH methods for efficacy in removing C. difficile
Design: Randomized crossover comparison among 10 volunteers experimentally contaminated by 1.4x10⁶ C. difficile (62% spores)
Methods: Interventions were evaluated for mean reduction
Conclusion: Handwashing with soap and water showed the greatest efficacy in removing C. difficile and should be performed preferentially over the use of alcohol-based hand rubs when contact with C. difficile is suspected or likely

Antisepsis to Prevent C. difficile Infections

YES!!

NO!!

Contact Precautions

- Wash hands before entering room
- Wash hands after leaving room
- Use alcohol-based hand rubs
- Wear gloves when indicated

Precauciones de Contacto

- Lave las manos antes de entrar. Lave después de salir.
- Limpieza con alcohol.
- Use guantes cuando sea necesario.
Conclusions

**Clostridium difficile**

- Have been found in abundance in the environment of individuals with disease
- Have been found on the hands of healthcare workers providing care to affected patients or touching the contaminated environment
- Survive in the environment (months [spores])
- Are relatively resistant to chemical disinfection (including alcohol)
- Have caused outbreaks in hospitals
- Are transmitted by either ingestion or direct inoculation of the GI tract
- Have epidemiological evidence that environmental surface contamination may be a source for infections

---

**Environmental control**

- In general, changes in disinfectants to eliminate specific pathogens not required.
- Because C. difficile spores are resistant to many surface disinfectants, care must be taken to use agents with evidence of efficacy (e.g., hypochlorite-based products). Ensure all surfaces are disinfected and all equipment is assigned.
- Current high-level disinfection recommendations are adequate to prevent healthcare-associated infections via semicritical items such as endoscopes.
- Areas with high endemic or epidemic C. difficile (e.g., 3 cases/1000 patient days) warrant hypochlorite-based products or room decontamination units (HPV or UV).
- Soap and water should be used preferentially to alcohol-based hand rubs for C. difficile.

---

**Microbiology and epidemiology of C. difficile**

- Role of the environment in transmission

**Prevention**

- Disinfectants for environmental disinfection (chlorine, HPV, UV)
- Disinfectants for semicritical equipment disinfection (HLD such as glut, OPA, PA)
- Antiseptics (not active against C. difficile spores [soap and water removal])
- Hand hygiene (soap and water [removal] not alcohol-based hand rubs)
